SECTION A

Establishing the Context

Thestructuralfault-linesthatmadethe fork almost unavoidable

Setting the Scene

To understand why a group of unpaid volunteers chose to walk away from one of the world's most successful open-source projects, you have to start about a decade before the actual split. In 1999, Sun Microsystems acquired a German company called Star Division and, in a move that genuinely surprised the industry, released its office suite—StarOffice—as open-source software under the name OpenOffice.org. The timing mattered. Microsoft Office had an iron grip on the desktop, its file formats were deliberately closed, and organisations in developing countries were essentially forced to pay for Windows-only software or be cut out of modern document exchange. OpenOffice.org broke that monopoly, at least theoretically. It was free to download, ran on Linux and macOS as well as Windows, and could open Word and Excel files. By the mid-2000s it had tens of millions of users and a community of contributors spanning the globe.

But there was a problem baked into the foundation from the very beginning, and it never really went away—it was simply tolerated, the way a slightly wobbly table leg is tolerated until someone drops something heavy on it.

TheStructuralFlaw:CopyrightAssignment

Every contributor to OpenOffice.org was required to sign a Joint Copyright Assignment (JCA) agreement with Sun Microsystems. This meant that a developer who spent their evenings fixing bugs or adding features did not retain the rights to their own work—Sun did. Sun also controlled the release schedule, the roadmap, and held an effective veto over which features made it into the product. Contributors could propose, build, debate, and submit patches, but the final word always rested with Sun's internal teams.

Many experienced contributors found this uncomfortable, even philosophically contradictory. The whole spirit of open-source development—particularly in the tradition of the Free Software Foundation—is that the community owns the commons. When a single corporation holds the copyright to code it largely did not write, that spirit is quietly violated, even if no license has technically been broken. The development pace also suffered. Decisions that a self-governing community could have resolved in a forum thread or a quick vote instead waited on Sun's internal approval processes, which moved at the speed of corporate bureaucracy.

Why did contributors stay? Partly habit, partly inertia, and partly because Sun—whatever its faults—was at least a company that seemed to believe in open source as something more than a line item. Sun had given the world Java, had championed Linux, and its engineers genuinely interacted with the OpenOffice.org community. The copyright assignment was uncomfortable, but Sun felt like a manageable steward. That calculation changed dramatically in January 2010.

Why Oracle Changed Everything

Oracle's $7.4 billion acquisition of Sun Microsystems brought an entirely different corporate personality into the picture. Oracle is primarily an enterprise database company whose business model depends on large support contracts and aggressive intellectual property enforcement. It is not, by any reasonable account, a company that views open-source community goodwill as a core asset. Within months of the acquisition, the signals were hard to ignore: Oracle launched a commercial product called Oracle Open Office, essentially reselling the community's work as a paid product; communication with the OpenOffice.org community became sparse and dismissive; and Oracle filed a landmark lawsuit against Google over Java usage in Android—the clearest possible signal of how Oracle intended to use the intellectual property rights it had inherited.

This is the key to understanding why the acquisition acted as a trigger when the copyright assignment problem had existed for years. The governance flaw had always been there. But risk is not just about the flaw—it is about who holds it. A creaky suspension bridge over a quiet stream is a nuisance; the same bridge over a gorge in a storm is a disaster waiting to happen. The copyright assignment that contributors had grudgingly signed with Sun now belonged to a company with a demonstrably aggressive posture toward intellectual property and open-source communities. The risk profile had changed completely, even though the legal documents had not.

Legal Openness Versus Practical Openness

The LibreOffice story draws a sharp line between two things that are often conflated: legal freedom and practical freedom. OpenOffice.org was licensed under the LGPL. Anyone could, in principle, read the code, modify it, and redistribute it. All four of the freedoms the Free Software Foundation defines were technically intact. Yet the project was functionally controlled by a single corporation. The community had no meaningful say in its direction, no ownership of the code they contributed, and no guaranteed path to independence.

Exercising the legal freedom to fork was always available—but it was never cheap. It meant abandoning years of accumulated infrastructure, splitting a community, confusing users, and rebuilding governance from scratch. Legal openness gave the community an escape hatch; it did not give them the building they were standing in. That distinction is, I think, one of the most underappreciated lessons of modern open-source history.

SECTION B

The Ethics of Corporate Control

Doesinvestmentjustifyauthority?Adefenceof community sovereignty

The Corporate Investment Argument

The most coherent argument in favour of corporate control over an open-source project goes something like this: open-source software does not build itself. Someone has to pay for servers, legal counsel, trademark registrations, and the full-time employees who do the unglamorous maintenance work that volunteers rarely want to touch. Sun paid those costs for OpenOffice.org for over a decade. It is not obviously unreasonable, the argument goes, for the entity bearing those costs to want governance authority in return. Corporations operate in legal and financial environments that require accountability, and accountability requires control.

There is something to this. A community of volunteers is not, in itself, a legal entity. It cannot sign contracts, hold trademarks, or be sued. The organisational scaffolding that makes a large release open-source project viable—foundation status, trademark protection, infrastructure—has to come from somewhere, and historically it has often come from corporations. Asking companies to fund that scaffolding while having no say in how the project is run is, at minimum, a difficult sell.

TheCommunityCommonsArgument—andWhy I FindItMorePersuasive

And yet I think the corporate control argument ultimately fails, for a reason that has nothing to do with ingratitude or anti-corporate sentiment.

When thousands of developers contribute their work to an open-source project, they are not doing so as employees of the company that hosts it. They are making what amounts to a gift to a commons—a shared resource that, by its nature, belongs to everyone who participates in and benefits from it. The corporation that hosts the project is, at best, a steward of that commons. A steward manages something on behalf of others; an owner manages it for themselves. These are fundamentally different relationships.
When Sun required copyright assignment, it was not just asking for administrative convenience. It was converting a stewardship relationship into an ownership relationship, without fully disclosing the implications to contributors. A developer contributing their first patch to OpenOffice.org in 2005 was, in effect, signing over their work to a company that could later sell it—which is exactly what happened when Sun sold itself to Oracle. The contributor did not consent to enriching Oracle. They consented to contributing to an open-source office suite that they believed would remain a community resource.

This is not a trivial distinction. It is the difference between contributing to a public library and donating books to a private collector who has promised to let the public in for now. The collector's promise may be sincere, but the legal reality is very different.

The Copyright Assignment Clause: Sun vs Oracle

Was Sun's copyright assignment requirement ethical? My honest answer is: marginally defensible, but poorly designed. Sun's motivations for requiring it were partly practical—it simplified legal defence of the codebase—and partly self-interested, since it preserved Sun's ability to relicense or sell the code. A more honest governance structure would have transferred those rights to an independent foundation from the start, as The Document Foundation eventually did with LibreOffice. The fact that Sun chose not to do this was a governance failure, even if it was not an act of deliberate bad faith.

The Oracle situation is different in kind, not just in degree. By the time Oracle acquired Sun, the open-source community had ample evidence of Oracle's approach to intellectual property. To continue requiring copyright assignment to Oracle—after the Java lawsuit against Google, after the launch of a commercial resale product, after months of dismissive communication—was not a defensible position. It was asking contributors to surrender their legal rights to an entity that had already demonstrated it would use those rights aggressively. I think that is ethically indefensible, regardless of what any contract said.

Stewardship vs Ownership: Is There a Meaningful Distinction?

Yes, and the LibreOffice case is perhaps the clearest proof that the distinction matters enormously in practice. A steward holds something in trust for a community and is accountable to that community. An owner holds something for themselves and is accountable only to their own interests. The Document Foundation's governance model—with its caps on corporate steering board representation, its contributor copyright retention, and its elected committees—is a concrete attempt to institutionalise the stewardship model. Oracle's management of OpenOffice.org was a concrete example of the ownership model in action.

The lesson I draw from this is that the stewardship/ownership distinction should not be left to goodwill or corporate culture. It has to be written into the governance structure with teeth. Goodwill expires; legal structures endure.

SECTION C

The Forking Question

Waswalkingawaytherightmove—and what did it cost?

Was Forking the Right Response?

Before defending the fork, let me make the strongest possible case against it, because I think the counter-argument deserves a proper hearing.

The argument against forking in 2010 would have gone something like this: Oracle had done nothing legally wrong. The copyright assignment was in the JCA that contributors had signed. The community still had all four software freedoms. Oracle had not threatened to close the codebase, had not sued the community, and had not changed the license. Moreover, a fork was guaranteed to damage the project in the short term—splitting developer effort, confusing users, and creating two competing products where there had been one. Governments and enterprises that had standardised on OpenOffice.org would now face an uncertain choice. The fork would fragment exactly the user base that the open-source office suite needed to maintain political and institutional momentum against Microsoft Office.

There is something to this. A more patient community might have tried harder to negotiate with Oracle—perhaps offering to take on the legal and infrastructure costs themselves in exchange for governance independence. The Document Foundation did invite Oracle to donate the OpenOffice.org brand and join the new structure, which was a reasonable offer, but the invitation came as part of a fork announcement rather than as a prior negotiation. It is at least possible that a more diplomatic approach—a formal written proposal, a period of good-faith negotiation, a clear ultimatum before action—might have produced a different outcome.

I find this argument ultimately unpersuasive, though not entirely without merit. The community had been watching Oracle's behaviour for months before the fork was announced. The Java lawsuit against Google was not a subtle signal. Oracle's handling of MySQL (discussed in Section D) was already visible. The open-source community is not politically naive—its members read corporate behaviour accurately, even when they cannot be certain of future actions. Waiting for Oracle to do something provably catastrophic before acting would have been strategically sensible only if the community believed Oracle would eventually change course. The evidence did not support that belief.

Oracle's Decisionto Decline:Business Logic vs Ethics

Oracle's refusal to donate the OpenOffice.org brand to The Document Foundation is, from a narrow business perspective, entirely rational. A commercial company does not typically donate a strategic asset to a competing community organisation, especially one that has just publicly questioned its trustworthiness. The brand had commercial value—Oracle was already using it to sell support contracts. Handing it over would have been a unilateral concession that Oracle's management had no incentive to make.

But the business perspective and the ethical perspective produce very different answers here. Ethically, Oracle held a brand and a codebase that had been built primarily by volunteers who had not intended to build something for Oracle's benefit. Refusing to facilitate an independent community structure for that work—and instead demanding that community members resign from the governance council if they wished to stay—was a choice to prioritise corporate asset protection over the wellbeing of the community that had actually created the value. Those two perspectives do not produce the same answer. The business logic was coherent; the ethics were not.

WastheForkWorththeFragmentation?

In retrospect, clearly yes. LibreOffice now has over 200 million active users. It is the default office suite on virtually every Linux distribution. Governments in Germany, Italy, and several Indian states have mandated or recommended its use. Apache OpenOffice, the continuation of Oracle's codebase, has a fraction of LibreOffice's contributor activity and has not released a major version update in years. The fragmentation was real and the confusion was real, but it was temporary. The resulting community health is not temporary—it is the new baseline.

There is a broader point here about how we evaluate the cost of principle. The short-term cost of the fork—user confusion, split development effort, institutional uncertainty—was real and should not be minimised. But if the community had stayed under Oracle's governance, what would they have been preserving? A project whose direction they did not control, whose code they did not own, and whose steward had already shown what kind of company it was. The fork did not create a problem; it surfaced one that already existed.

SECTION D

Lessons and Generalisation

WhatLibreOfficeteachesusaboutcorporate open source at scale

The MySQL Parallel and What Two Forks Tell Us

The fact that MySQL was forked into MariaDB at almost exactly the same time, by almost the same logic, and triggered by almost the same corporate acquisition, is not a coincidence. It is a pattern, and patterns are more informative than individual events.

Michael Widenius, MySQL's original creator, had already sold MySQL AB to Sun in 2008. When Oracle acquired Sun, he did not wait to see how Oracle would handle the community—he forked MySQL into MariaDB before the acquisition was even finalised. MariaDB is now the default MySQL-compatible database on most Linux distributions. Many developers use it without realising they are not using the original MySQL.

Two major open-source projects, two forks, one acquisition, one corporate acquirer. The message this sends about the relationship between corporate ownership and open-source community health is fairly stark: communities that have built their governance structures on trust in a single corporate steward are structurally fragile. When that steward changes—through acquisition, leadership change, or strategic pivot—the community has no institutional protection. The freedom the license provides is real but insufficient. What the license cannot give you is governance.

The Hypothetical: Company X and the Cloud Project

Consider the scenario described in the assignment: Company X contributes the majority of code to a popular open-source project, controls its governance, and uses the project's success to attract customers to its commercial cloud services. Is this meaningfully different from the Oracle/OpenOffice.org situation?

It is different in texture but not in structure. The Oracle situation was overtly antagonistic; the Company X scenario sounds benign because X is contributing code and the project is thriving. But the structural risk is identical: a single corporate entity controls governance and holds disproportionate influence over a project that presents itself as a community resource. The community's ability to govern itself does not depend on Company X being well-intentioned—it depends on whether the governance structure would survive Company X becoming badly intentioned, being acquired, or changing strategic direction.

The criteria I would use to evaluate whether a corporate steward can be trusted are:

- Does any single company control more than a minority share of the governance board?
- Do contributors retain copyright on their own contributions, or must they assign it to the corporation?
- Is the decision-making process—roadmap, release schedule, conflict resolution—documented, public, and enforceable?

- Does the governance structure have legal permanence independent of the company's existence?
- What happens to the project if the company is acquired, goes bankrupt, or simply loses interest?

If the answers to these questions rely primarily on the goodwill of the current corporate leadership, the project is one bad acquisition away from a crisis.

GovernanceRecommendationsforaNew Project

If I were advising developers starting a new open-source project today, I would recommend a governance structure built on three non-negotiable principles.

First, establish an independent legal entity immediately. Not after the project becomes successful, not when corporate sponsorship arrives—immediately. This entity should be a non-profit foundation in a jurisdiction with stable non-profit law. Its charter should explicitly state that no single corporate entity may control more than a defined minority of the governing board. The Document Foundation's one-third cap is a reasonable model.

Second, never require copyright assignment. Contributors should retain full copyright over their contributions. The project can request a patent licence from contributors (as the Apache License 2.0 does) without requiring copyright transfer. This single change eliminates the most dangerous structural vulnerability in the OpenOffice.org model.

Third, make all governance decisions in public and by documented process. Roadmap decisions, release authority, and conflict resolution should be handled by elected or merit-based committees whose processes are written down and enforced by the foundation's charter. Corporate sponsors should be explicitly welcome and explicitly limited: they can contribute code, fund infrastructure, and be represented on the board—up to the minority cap.

SECTION E

Personal Reflection

Whatthisstorychangedinhow I think about open source

Before I read through this case study properly, I think my mental model of open source was mostly technical. Open source meant you could see the code, download it for free, and probably modify it if you knew what you were doing. The politics, the governance structures, the copyright law—that was background noise, the sort of thing lawyers worried about. The code was the thing.

What surprised me most was not Oracle's behaviour—that, in retrospect, seems predictable for a company of that type. What surprised me was how long the community tolerated the copyright assignment requirement under Sun, knowing it was structurally dangerous. It is easy to read that history and think: how could they not see it coming? But I think I understand it. When something is working—when the project is growing, when the code is good, when the steward is relatively benign—the structural risk feels abstract. The wobbly table leg is a problem for another day. That is a very human thing, and I do not think developers are uniquely vulnerable to it.

What troubles me is the copyright assignment clause itself—not as a legal mechanism, but as a social one. Thousands of people gave their time, skills, and creativity to something they believed was a commons. They were not wrong to believe that; it behaved like a commons for years. But the legal reality was always different from the social reality, and when a corporate acquisition made that gap visible, they had to pay a real cost to close it. That feels genuinely unfair to me—not illegal, not even necessarily dishonest, but unfair in the way that matters: people acted in good faith and the structure did not protect them.

Would I have made the same choice as the LibreOffice founders? I want to say yes. Principle over convenience is easy to endorse in the abstract. But I am also honest enough to acknowledge that walking away from years of work, from an established user base, from existing infrastructure—for an idea, essentially—takes a kind of conviction that is harder in practice than in theory. What the founders did was not just technically possible; it was genuinely brave in the way that any bet on principle over pragmatism is brave.

The thing I will carry from this case study is simpler than any of the governance theory: the legal structure of a project is not a detail to sort out later. It is the first decision, because every other decision flows from it. Who owns the code, who decides the direction, who can veto a release—these are not bureaucratic questions. They are questions about whose project it actually is. The LibreOffice community asked that question when it was almost too late. The answer cost them two years of fragmentation and confusion. But the answer was right, and they were right to insist on it.
